SimBorgs

Towards the Building of Simulated Human Users for Interactive System Design

Wayne D. Gray

Michael J. Schoelles

SimBorgs

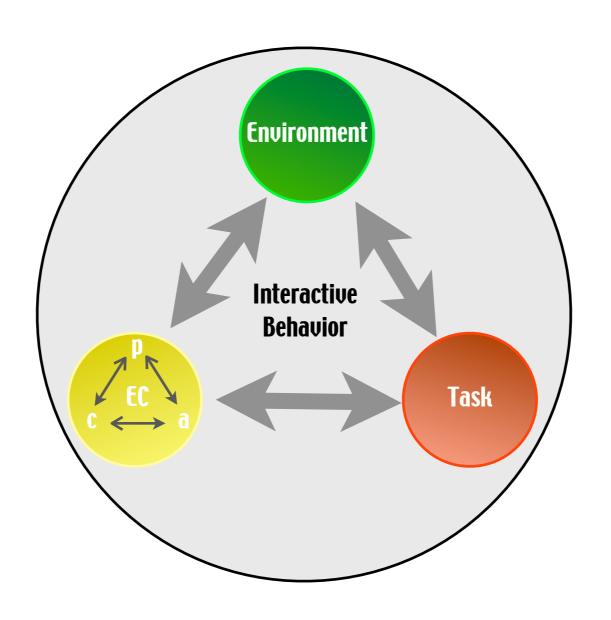

- SimBorg = Simulated Cyborgs
- Cyborgs = part human & part machine
- For SimBorgs
 - O The machine part is real
 - O The human part is simulated in ACT-R (hence the name)

Issues & Motivations

- Seeking to interact with task environments built by other people, running on other machines (see Schoelles' presentation at this afternoon's symposium)
- Looking to transition our basic research into engineering applications
- How to apply cognitive theory to interactive system design?
- Why is so little of this sort of thing done now?

The Interactive Behavior Triad

Goal

To separate the low-level acquisition and interactive processes specific to the design of the task environment from higher-level, task-specific expertise

What is the problem we are trying to solve?

- For a simulated human user to be useful in testing interface designs how much of human behavior must be simulated in a cognitively plausible manner?
- The Problem
 - Task knowledge and even cognitive processes are very task-specific (as per Ericsson & Kintsch, 1995)
 - O How much of human expertise do we need to model in order to develop computational cognitive models capable of being used as tools for design and usability testing?

A Way Out?

- Many instances where we can match (or exceed) human expert performance by very non-human means
 - O Deep Blue
 - O Statistical techniques such as multiple regression
 - O Math modeling
 - O etc
- Possible to finesse the expertise issue by turning the reasoning component over to a black-box module
 - O No claims made about the cognitive fidelity of the processing of the module

A 3-Tier Architecture for Interactive System Design

Tier C -- Black-Box Module

Tier C Black-Box Module Tier C represents noncognitive methods that can be used to compute solutions to problems given the data contained in the schema(s). These may be machine-reasoning algorithms, multiple regression type stuff, simple mathematical formulas, Bayesian Networks, etc

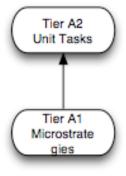

Tier C -- Black-Box Module

Tier B -- Knowledge Schema Module

Tier B Schemas Tier B represents the schemas used by experts for task performance. Think of this as long-term working memory in the E&K sense. These may be implemented as large DMEs or as regular size DMEs with lots of associative links.

Tier B -- Knowledge Schema Module

Tier A -- Interactive Behavior Module

Tier A spans two levels in a modified version of Newell's Time scale of human activity Tier A -- Interactive Behavior Module

A three tier architecture for building simBorgs

A 3-Tier Architecture for Interactive System Design

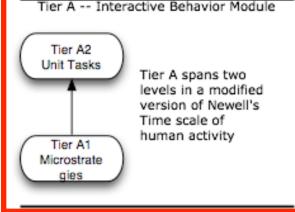

Tier C -- Black-Box Module

Tier C Black-Box Module

Tier C represents noncognitive methods that can be used to compute solutions to problems given the data contained in the schema(s). These may be machine-reasoning algorithms, multiple regression type stuff, simple mathematical formulas, Bayesian Networks, etc.

Tier B -- Knowledge Schema Module

Tier B Schemas Tier B represents the schemas used by experts for task performance. Think of this as long-term working memory in the E&K sense. These may be implemented as large DMEs or as regular size DMEs with lots of

A three tier architecture for building

Tier A -- Interactive Behavior Module

- Level of highest cognitive fidelity
- Interacts directly with the task environment the way that people interact with it

AI -- Microstrategy level

- Hard Constraints
- Greatest reusability of productions

A2 -- Unit task level

- Soft Constraints
- Driven by least-effort considerations

A 3-Tier Architecture for Interactive System Design

Tier C -- Black-Box Module

Tier C Black-Box Module

Tier C represents noncognitive methods that can be used to compute solutions to problems given the data contained in the schema(s). These may be machine-reasoning algorithms, multiple regression type stuff, simple mathematical formulas, Bayesian Networks, etc.

Tier B -- Knowledge Schema Module

Tier B Schemas

Tier B represents the schemas used by experts for task performance. Think of this as long-term working memory in the E&K sense. These may be implemented as large DMEs or as regular size DMEs with lots of associative links. Tier Δ -- Interactive Behavior Module

Tier A2 Unit Tasks Tier A spans two levels in a modified version of Newell's Time scale of human activity Tier A1 Microstrate aies

A three tier architecture for building

- Tier B -- Knowledge Schema Module
 - O Sets of scenario-specific schemas
 - Derived by knowledge engineering techniques from human experts as they solve a given scenario
 - O This level is based on modeling work with Project Nemo (Gray, 2003; in progress)
 - Schemas as E&K's long-term working memory knowledge structures

A 3-Tier Architecture for Interactive System Design

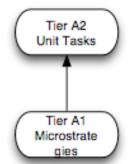

Tier C -- Black-Box Module

Tier C Black-Box Module Tier C represents noncognitive methods that can be used to compute solutions to problems given the data contained in the schema(s). These may be machine-reasoning algorithms, multiple regression type stuff, simple mathematical formulas, Bayesian Networks, etc

Tier B -- Knowledge Schema Module

Tier B Schemas Tier B represents the schemas used by experts for task performance. Think of this as long-term working memory in the E&K sense. These may be implemented as large DMEs or as regular size DMEs with lots of associative links.

Tier A -- Interactive Behavior Module

Tier A spans two levels in a modified version of Newell's Time scale of human activity

A three tier architecture for building simBorgs

Tier C -- Black-Box Module

- May contain a variety of methods for problem solving or reasoning
- Machine-reasoning algorithms, Bayesian networks, multiple regression models, or algebra equations that simply compute an answer
- O The method provides an answer the human might give, but the process bears no resemblance to human information processing

SimBorgs

GIGO

- O Black-box module will work perfectly -- to the limits of the information provided it by the other two modules
- Old information, wrong information, incomplete information will cause degradations in performance
- Holds the reasoning process constant
 - Provides a general way of exploring how differences in interface design lead people to trade off effectiveness for efficiency
- Goal: To be able to separate
 - O the low-level information acquisition and interactive processes specific to the design of a task environment, from
 - O the higher-level, problem-specific expertise required to do a particular job

Changes to ACT-R

- Addition of a Black-Box buffer
- To the extent that the other ACT-R buffers are grounded in neurocognitive data (Anderson, et al., 2002), then the black-box buffer may be regarded as a simulated brain implant

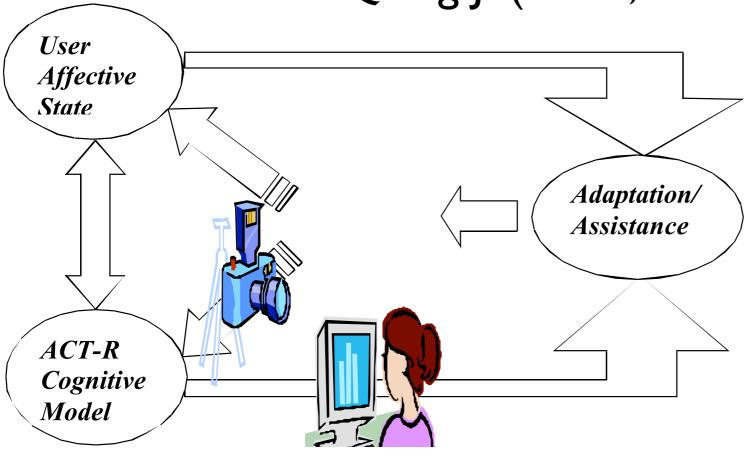

Other New Work

- ASAP -- Affective State Argus Prime
- Combining Powerful Technologies!
 - What can happen when you combine a system that can parse emotions in real-time with . . .

Affect-Sensitive Cognitive Modeling for User Assistance

with Qiang Ji (ECSE, Rensselaer)

S&TAreas

- O User affective state inference
- O Emotional ACT-R
- User assistance for performance enhancement

Technical Challenges:

- Represent and integrate uncertain and dynamic sensory data of different modalities over time to infer user state efficiently and timely
- Incorporate affect state into ACT-R in a principled way
- Opnically characterize the utility of an assistance and determine the best application timing
