

# Experience and Context Influence the Generation of Hypotheses from Memory

Katja Mehlhorn, Niels Taatgen, and Fokie Cnossen

# Hypothesis generation...

...is highly complex.

But people do it with high speed and accuracy.

How do they do that?

# People generate hypotheses that...

Were successfully used in  
previous experiences

Are supported by the  
current context

**Possibly related aspects of memory activation:**

**Base-level activation**

**Spreading activation**

Question:

Can we find evidence for  
**base-level activation** and  
**spreading activation**  
on **hypothesis generation?**

## Experiment – 3 tasks

Diagnose medical  
symptoms

Hypothesis generation  
from memory

React to visual  
stimuli

Manipulates base-levels of  
hypotheses in memory

Count (yes, no) a  
subset of the stimuli

Manipulates spreading activation  
to hypotheses in memory

# Diagnoses - Chemical accident task

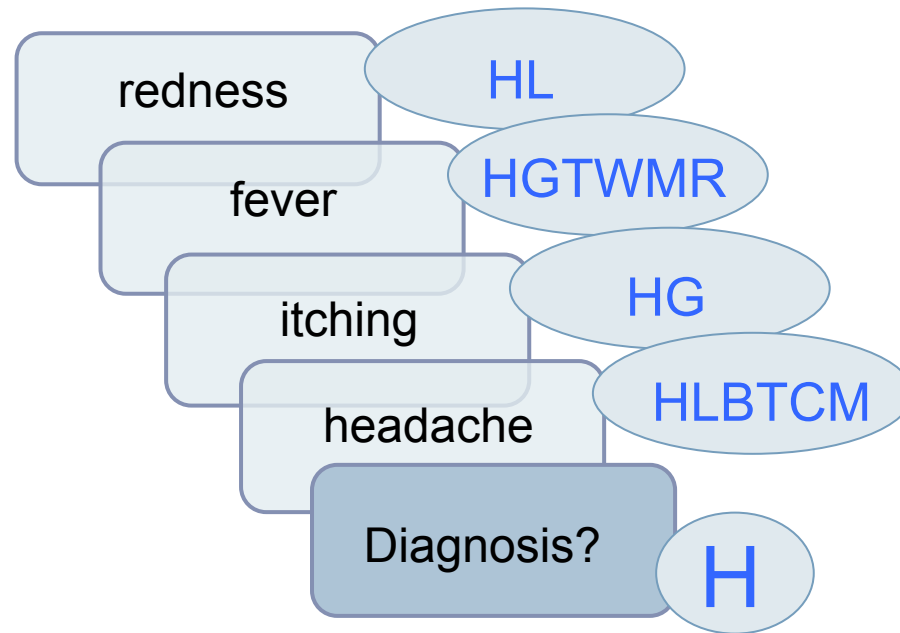

# Diagnostic knowledge

→ learned before the experiment

Source	Chemical	Specific symptoms			Unspecific symptoms		
inhaled	B	cough		short breath	headache		dizziness
	T	cough	sneezing		headache	fever	
	W		sneezing	short breath		fever	dizziness
skin contact	L	redness		rash	headache		dizziness
	H	redness	itching		headache	fever	
	G		itching	rash		fever	dizziness
drinking water	C	diarrhea		cramps	headache		dizziness
	M	diarrhea	vomiting		headache	fever	
	R		vomiting	cramps		fever	dizziness

# Diagnosis task

## Experiment – 3 tasks

Diagnose medical  
symptoms

Hypothesis generation  
from memory

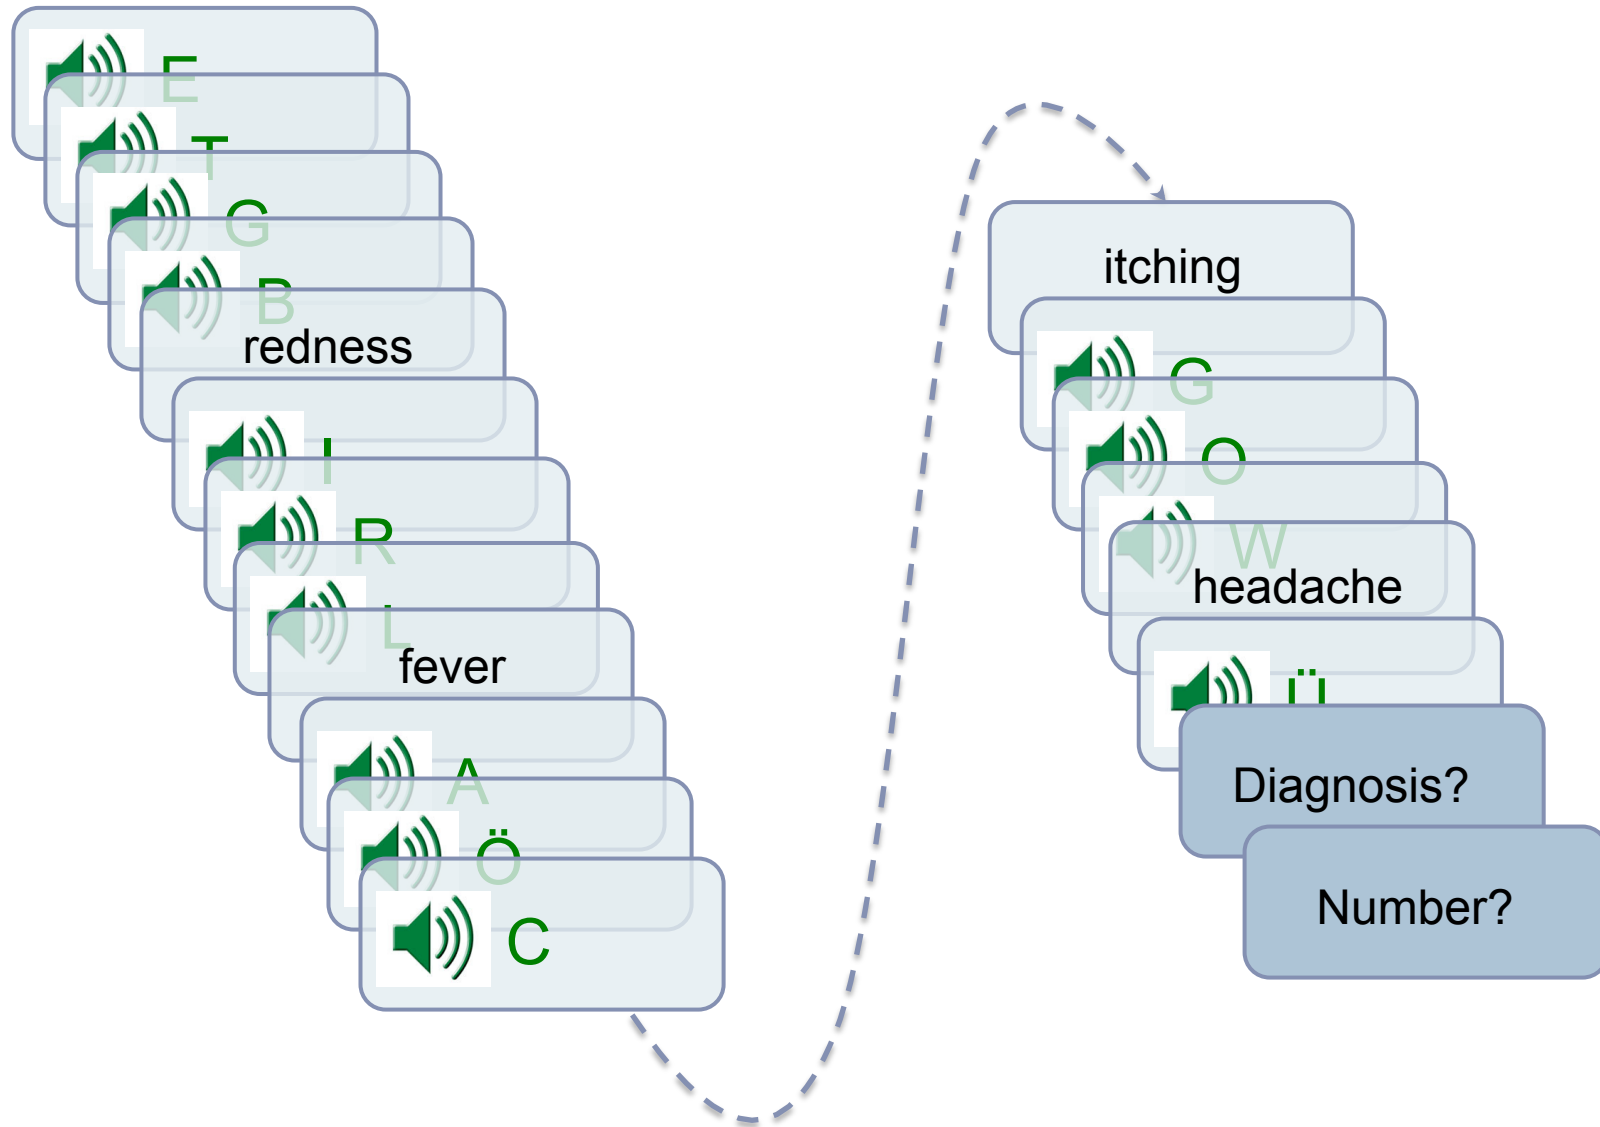

React to visual  
stimuli

Manipulates base-levels of  
hypotheses in memory

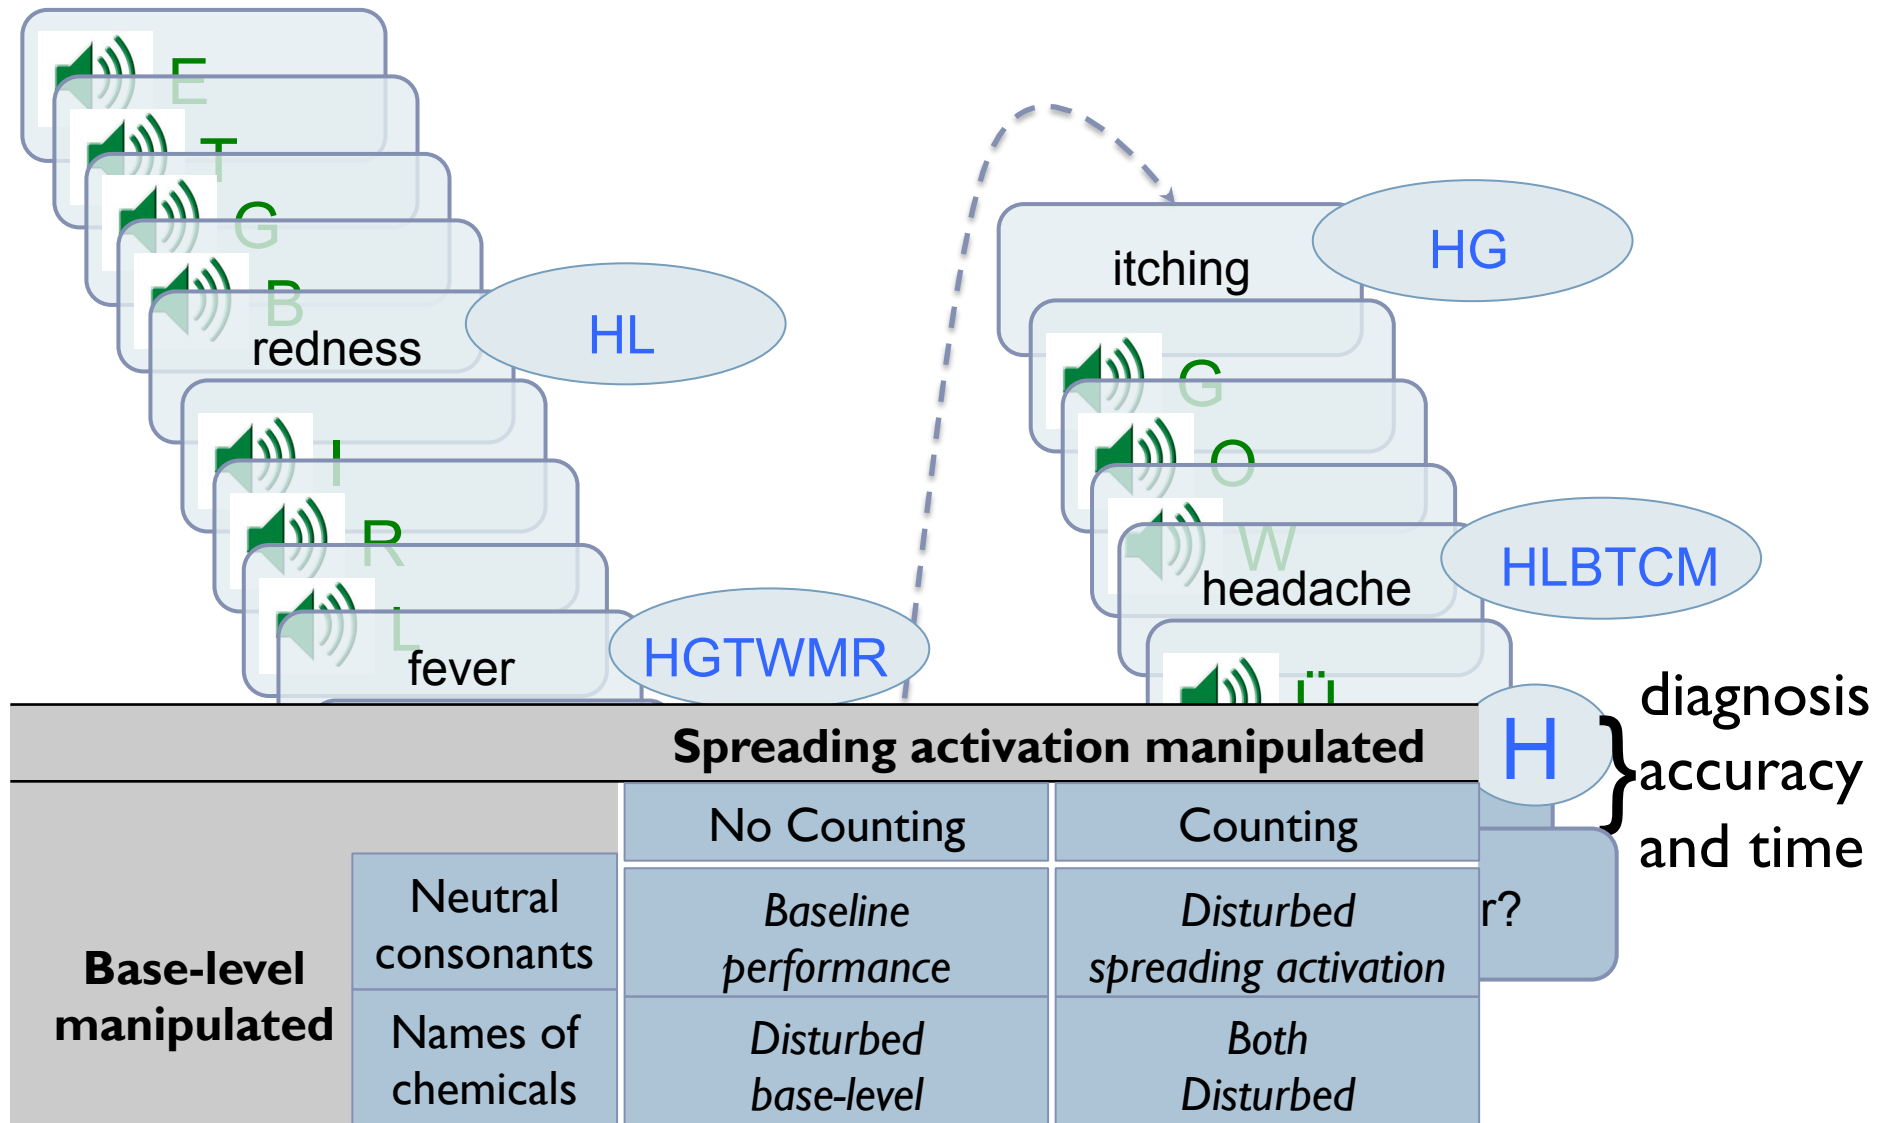

Count (yes, no) a  
subset of the stimuli

Manipulates spreading activation  
to hypotheses in memory

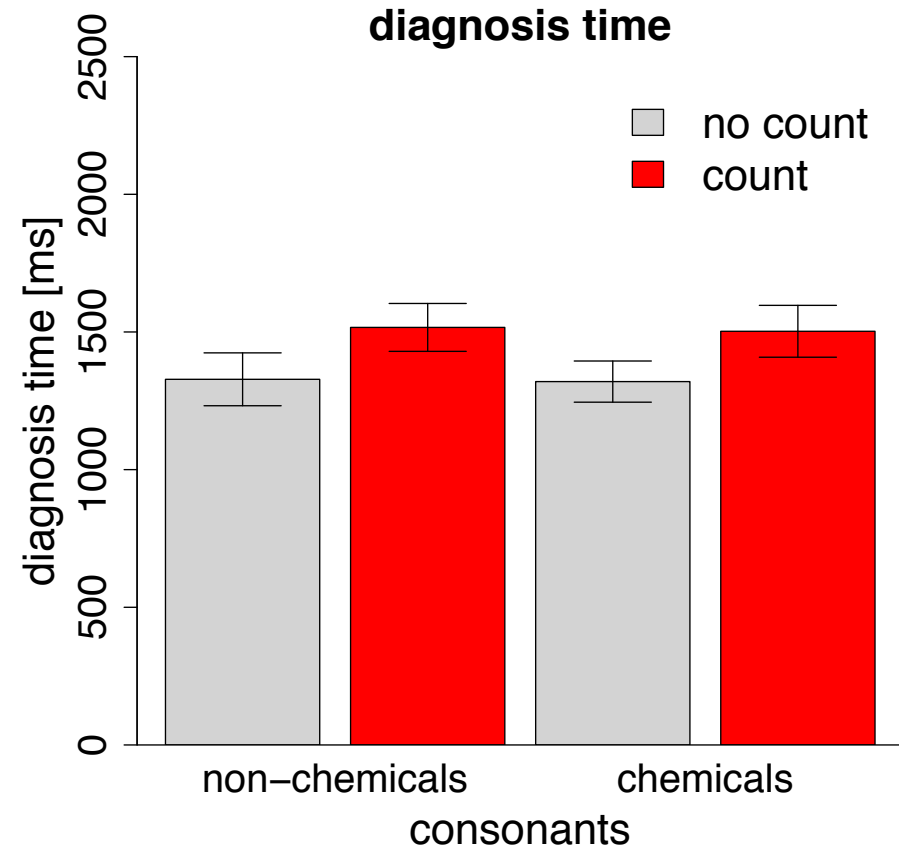

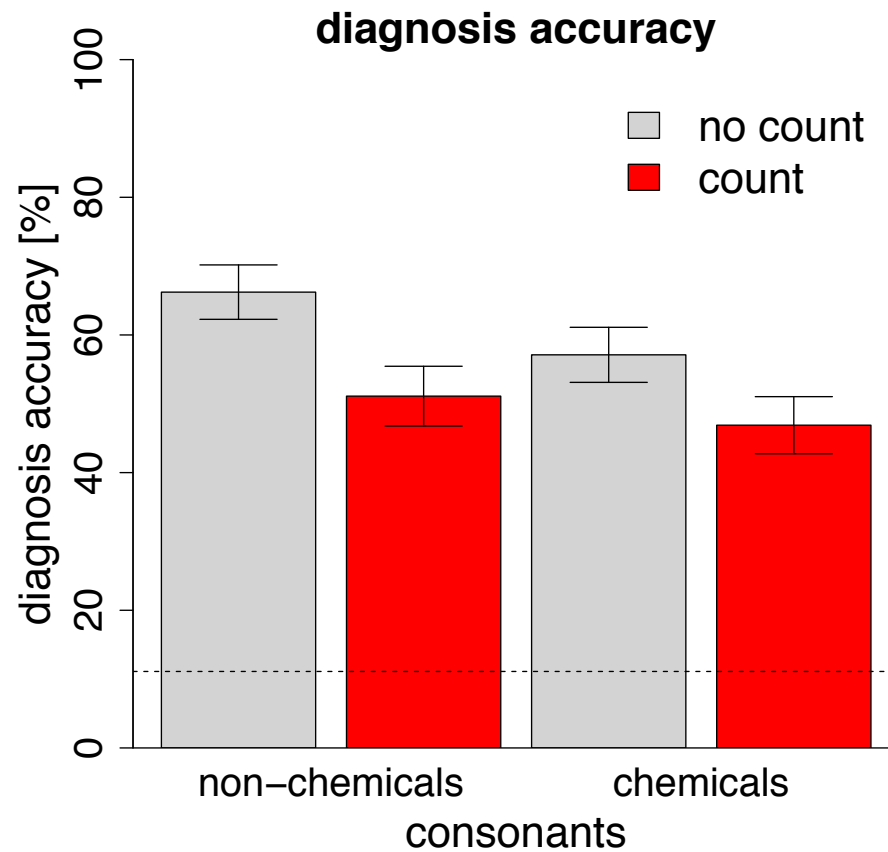

“diagnose & react to letters & count consonants”

“diagnose & react to letters & count consonants”

# Results Diagnosis Task

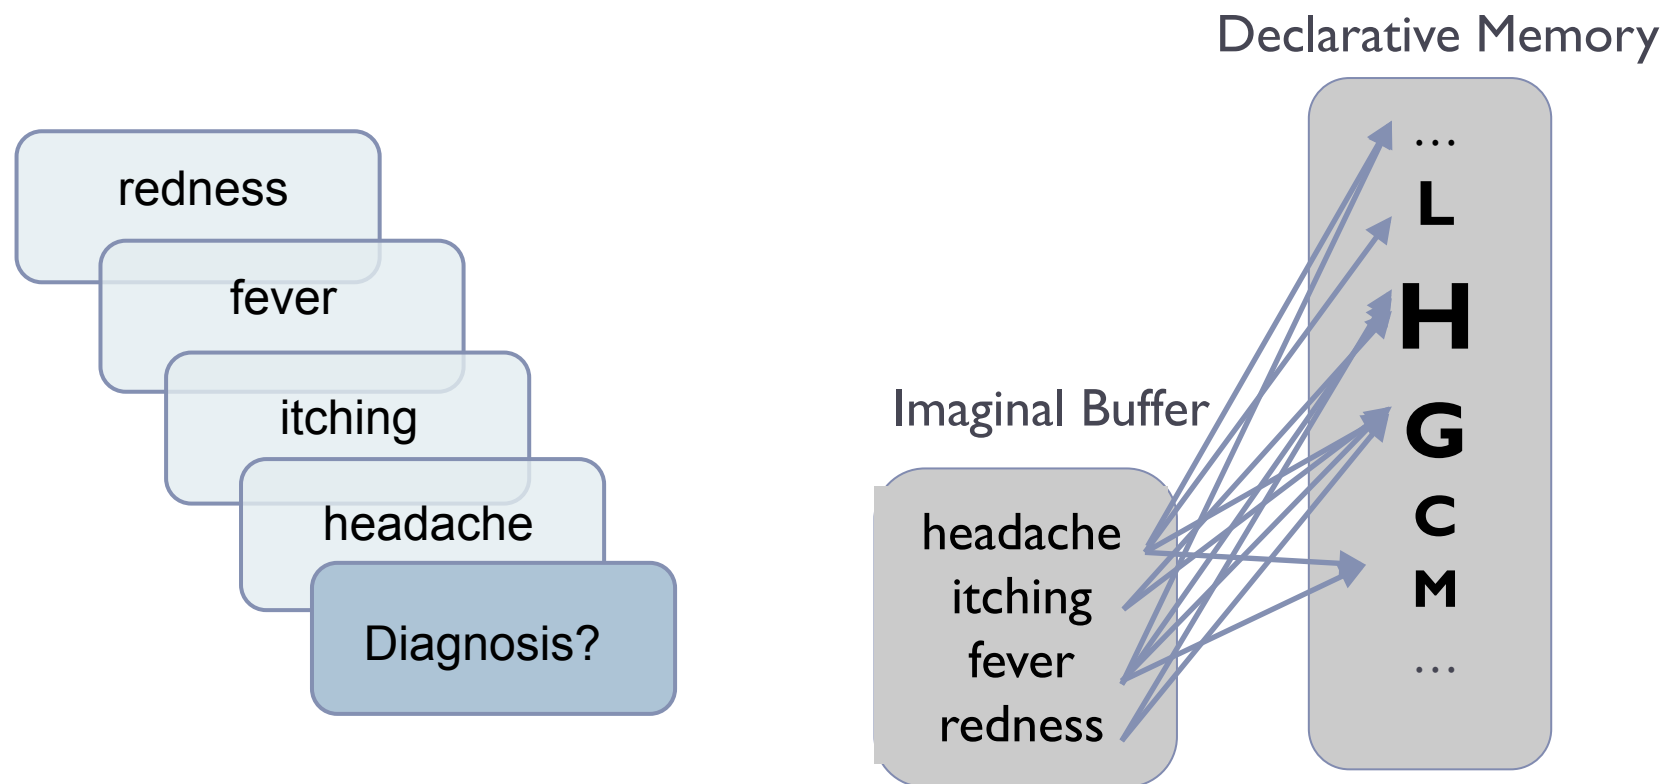

# ACT-R model

- ▶ Combination of existing models
  - ▶ Diagnoses: Spreading Activation Model (Mehlhorn et al., 2011, JEP: LMC)
  - ▶ Counting: Count Model (ACT-R tutorial)
  - ▶ Task-switching: Problem State Model (Borst et al., 2010, JEP: LMC)

## Diagnosis task in the model

→ Retrieve the most active explanation from memory

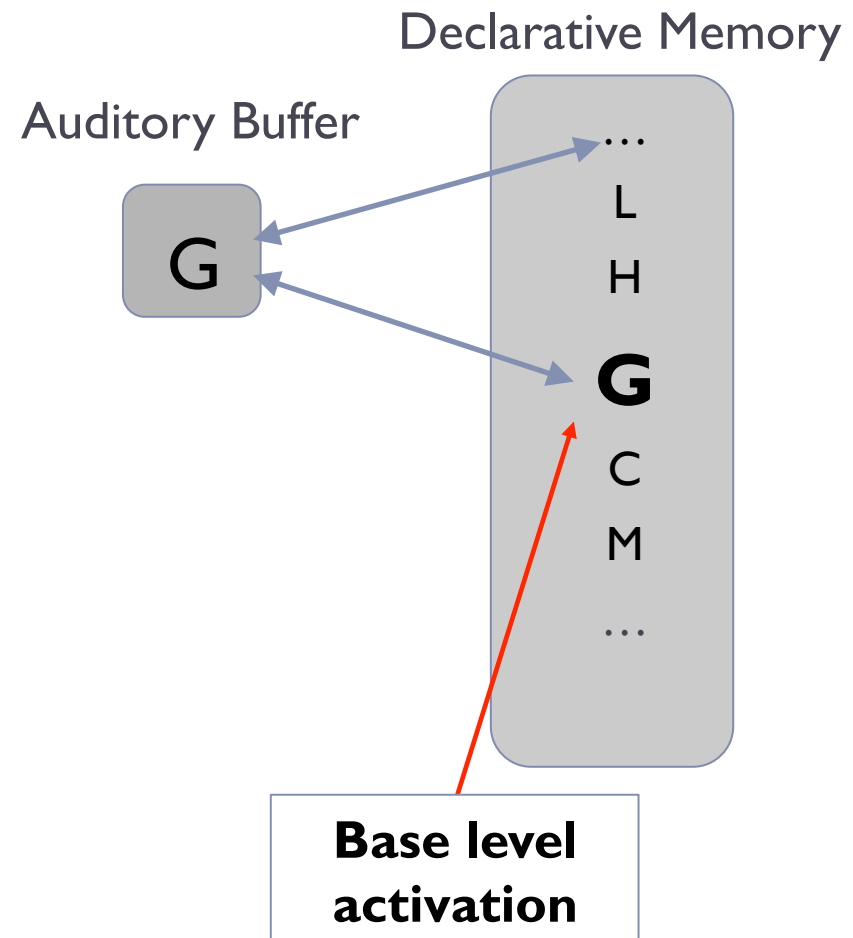

## Reaction task in the model

→ Indicate whether heard letter is a consonant or vowel

## Reaction task in the model

→ Indicate whether heard letter is a consonant or vowel

Counting task in the model

→ Count consonants

# Counting task in the model

→ Count consonants

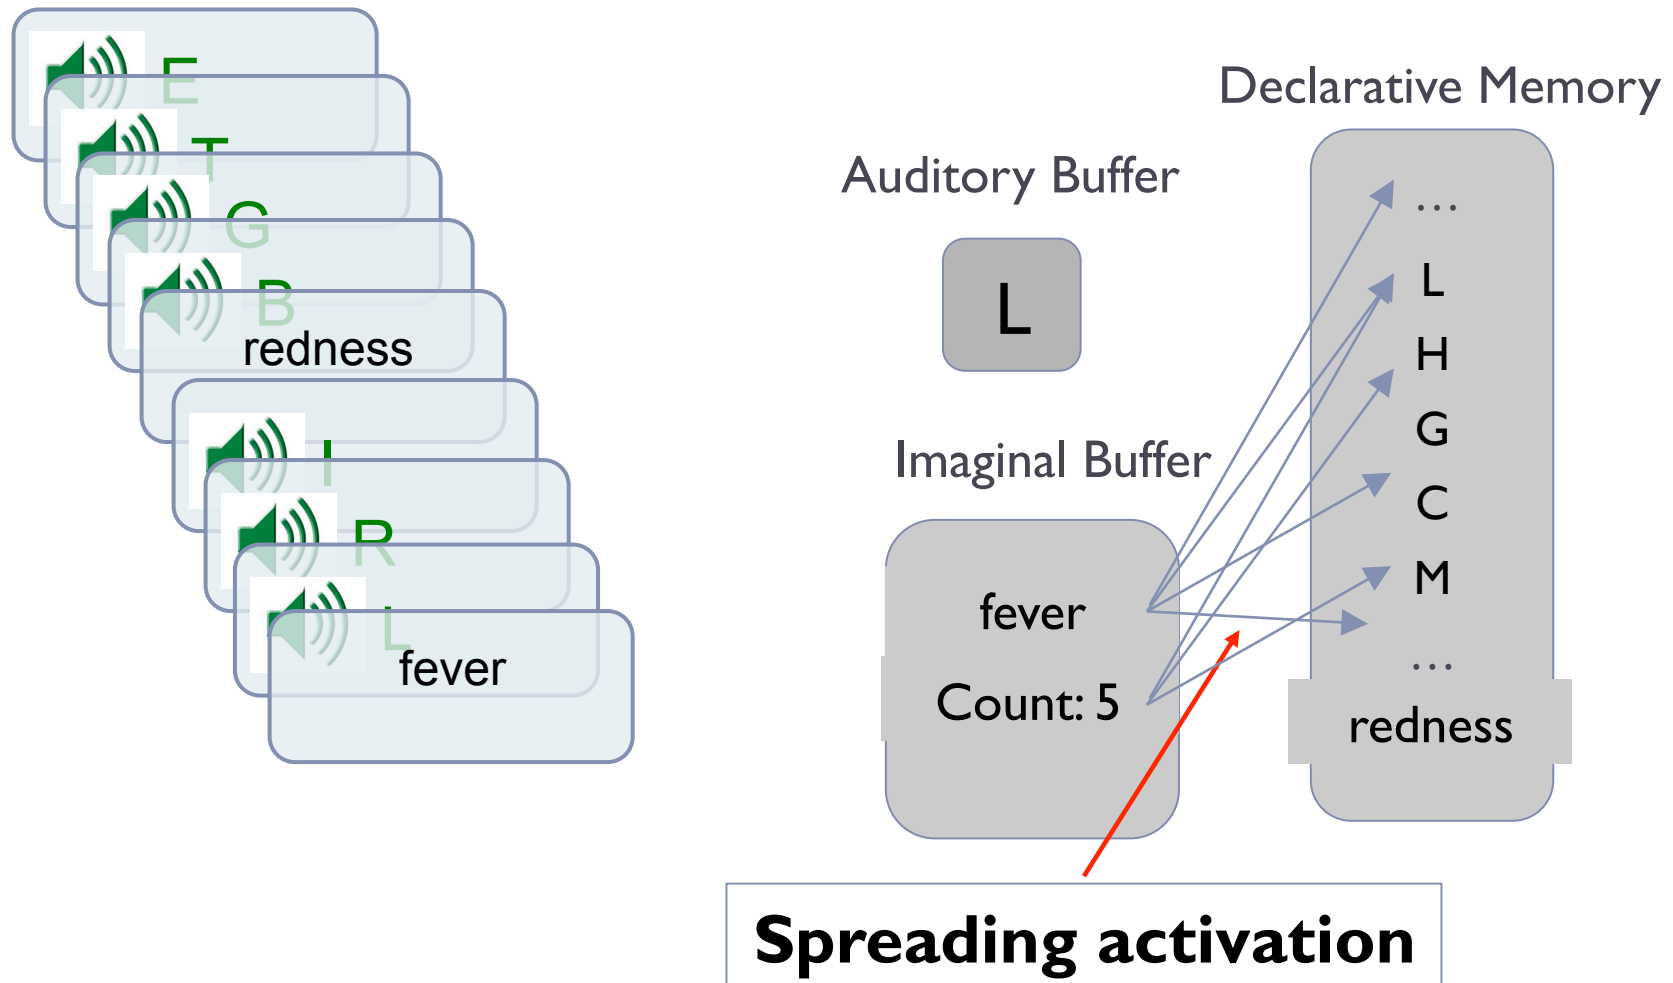

# Counting task in the model

→ Count consonants

# Counting task in the model

→ Count consonants

# Counting task in the model

→ Count consonants

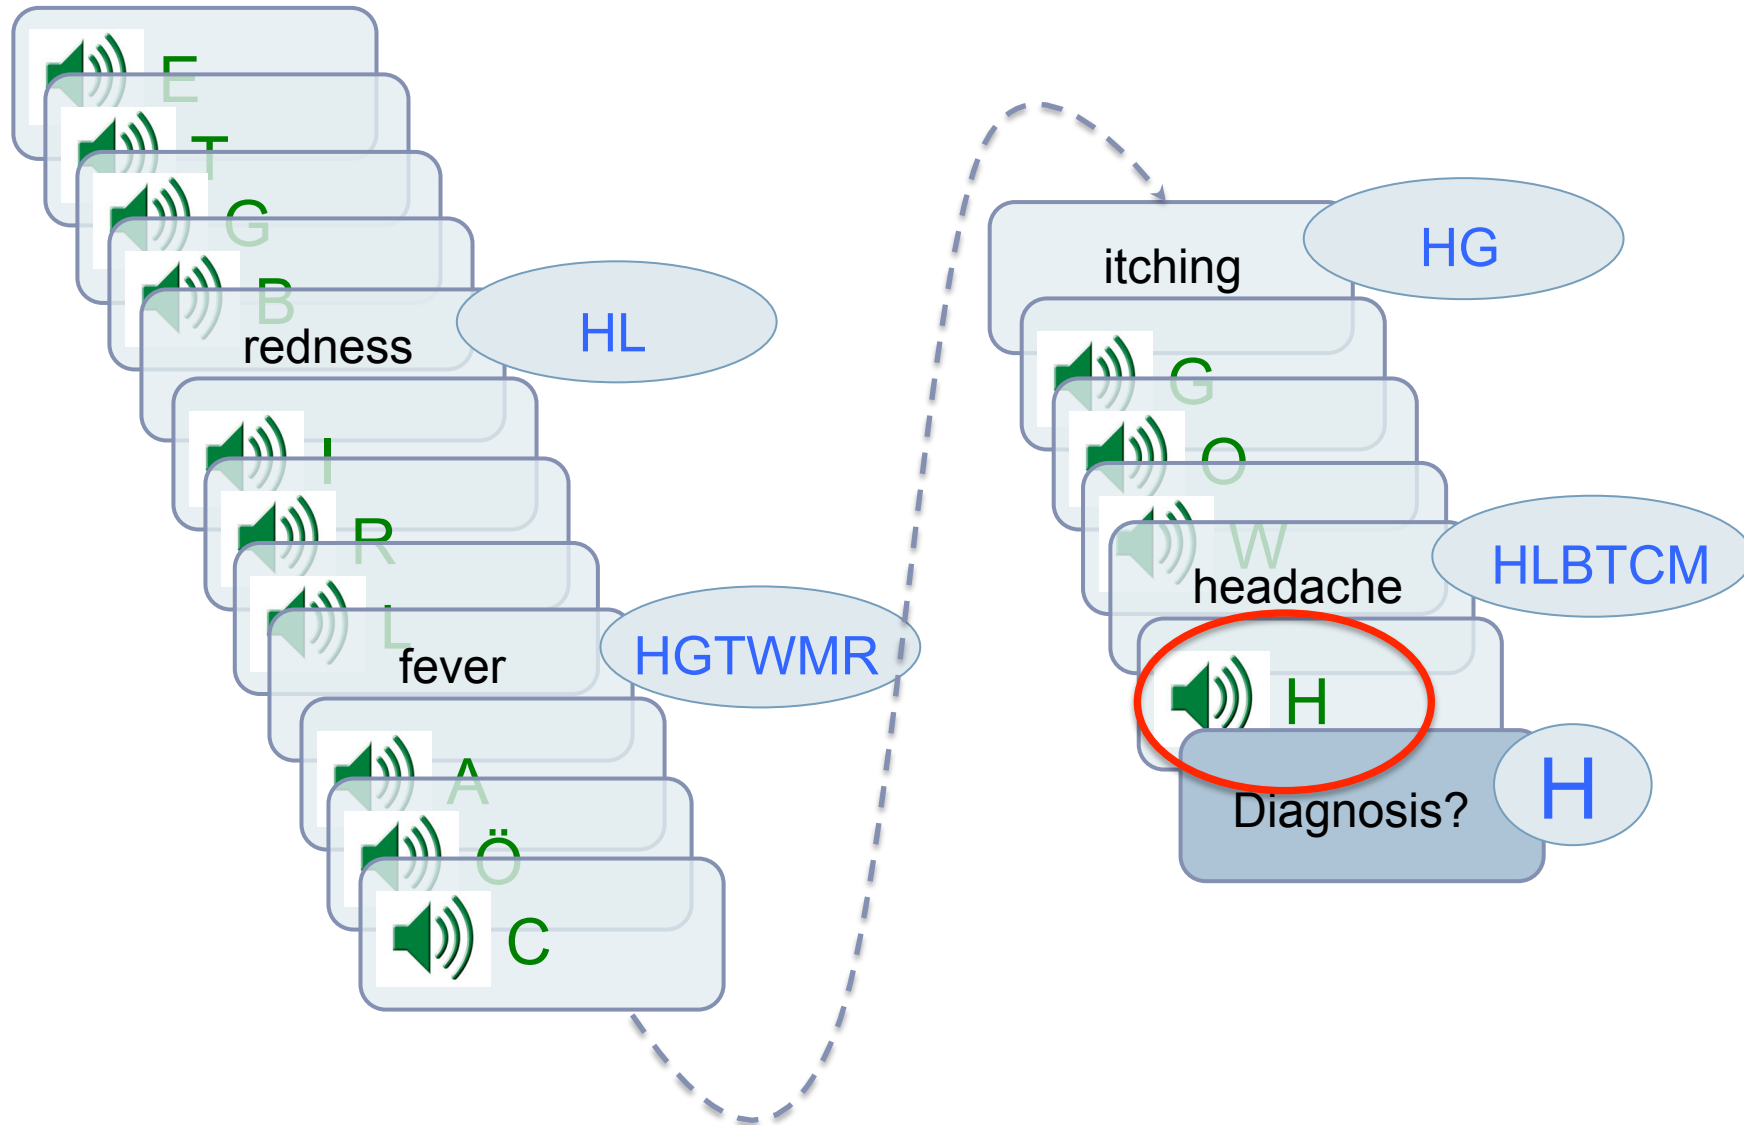

# Results Diagnosis Task – Model Fit

Can the correct diagnosis be primed?

Can the correct diagnosis be primed?

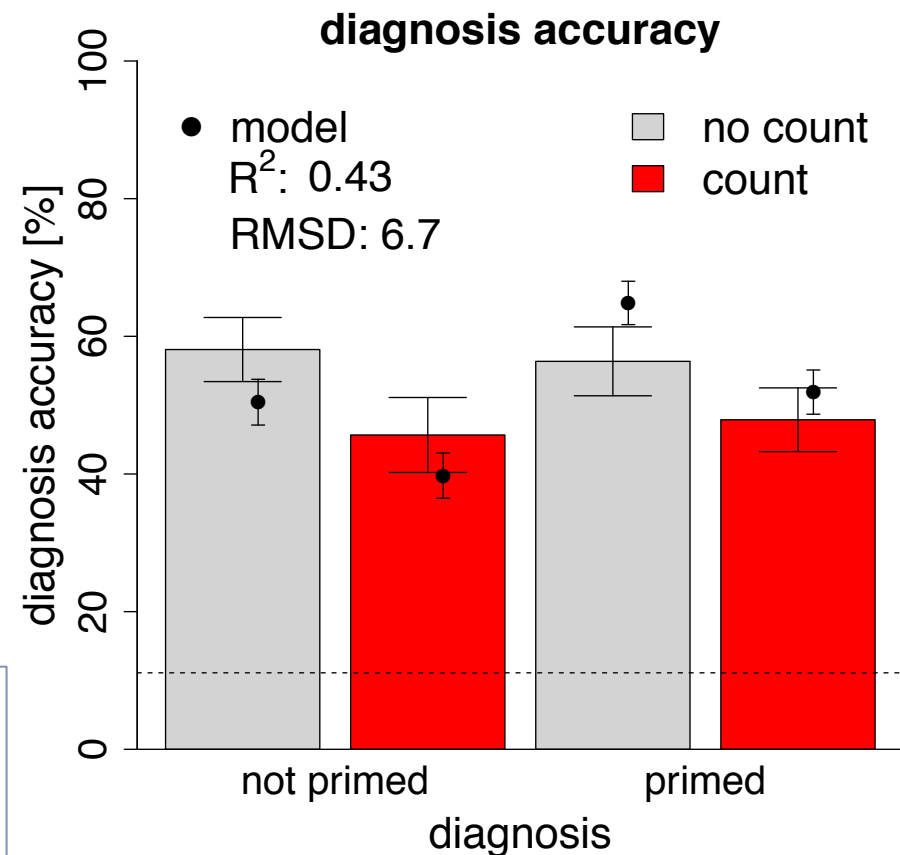

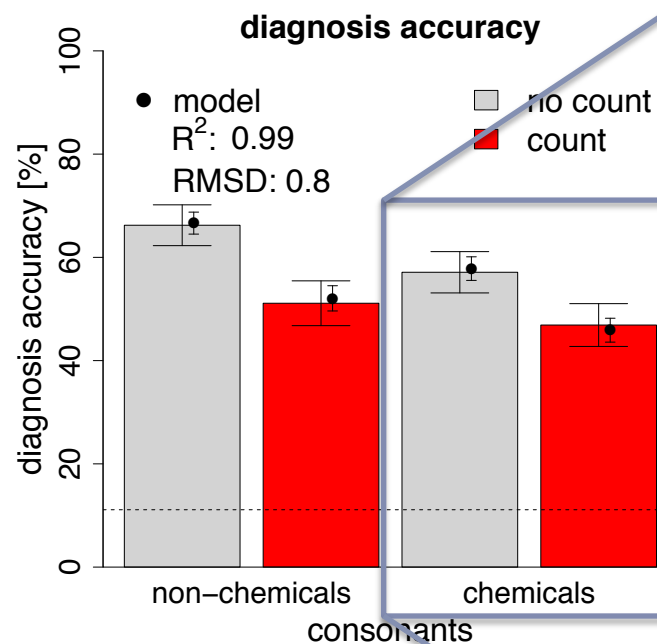

# Can the correct diagnosis be primed? - Accuracy

# Can the correct diagnosis be primed? - Accuracy

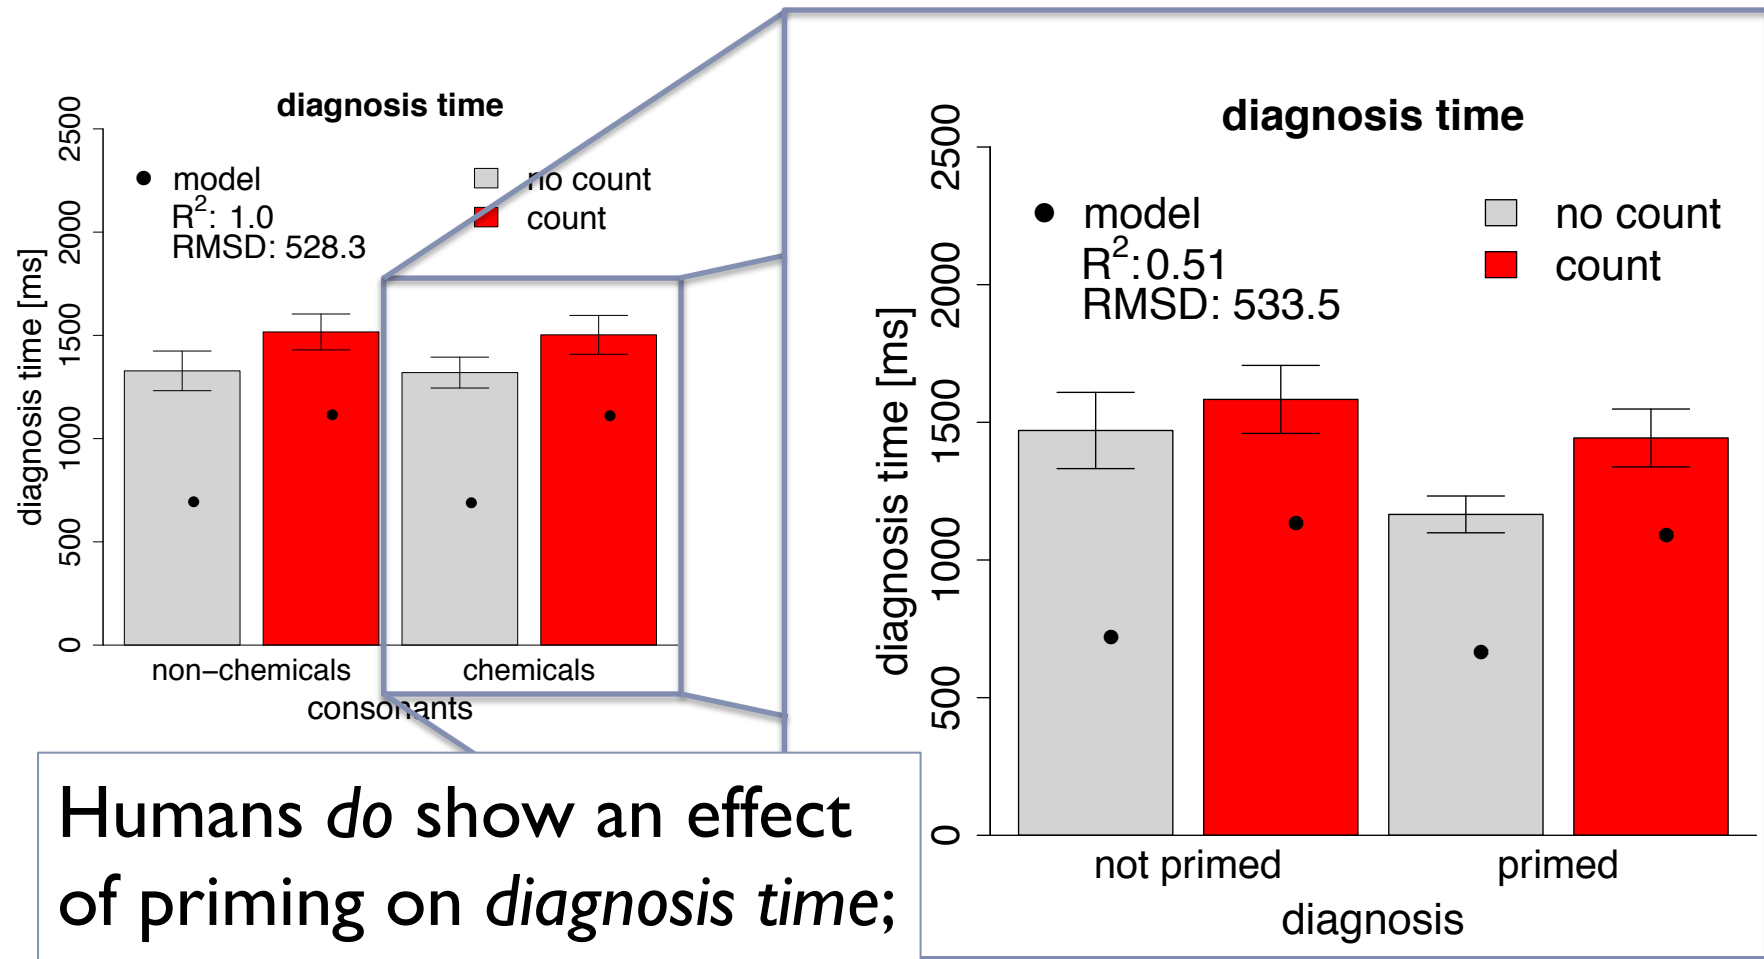

Humans *don't* show an effect of priming on *diagnosis accuracy*, but the model does

# Can the correct diagnosis be primed? - Time

# Can the correct diagnosis be primed? - Time

Humans *do* show an effect of priming on *diagnosis time*; the model does too, but less strongly

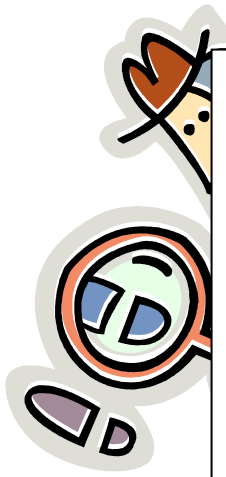

## Summary

- ▶ Our experiment shows main effects of both, the reaction task and the count task
- ▶ The model suggests that these affects might be due to the two aspects of memory activation proposed by ACT-R
  - ▶ However, the model has problems fitting the fine grained effects of priming on diagnosis accuracy

# Hypothesis generation...

# Conclusion

Memory activation helps people to generate hypotheses that are most likely to be needed in the light of **previous experiences** and the **current context**.
